

Nested Form (TASK 5)

Overview

Create a dynamic form using React where users can add questions and nested sub-questions dynamically. The form should allow multiple levels of questions (parent and child questions). You will also implement basic form submission to display the questions in a hierarchical view.

Core Features

1. Add New Parent Questions:
2. Implement an "Add New Question" button that allows users to dynamically add new questions
3. Each question should include:
 - a. A text input field to enter the question.
 - b. A dropdown to select the type of question: "Short Answer" or "True/False."
4. Add Nested Child Questions:
 - a. If a True/False question is selected and the answer is "True", show an option to add a child question.
 - b. Child questions can also have nested child questions (recursive nesting).
 - c. Child questions should have the same structure as parent questions (text input, dropdown).
5. Ensure auto-numbering in a hierarchical format (e.g., Q1, Q1.1, Q1.1.1, Q2).
6. Delete Functionality:
 - a. Each parent and child question should have a delete button that removes the question (including any child questions if it is a parent).
7. Auto-numbering:
 - a. Automatically number parent and child questions according to their position and depth (e.g., Q1, Q1.1, Q2).
8. Form Submission:
 - a. On submission, display all parent and child questions in a hierarchical format for review.
 - b. No backend or API integration is required, just display the results within the React app.

Bonus Challenges

Local Storage Persistence:

- Implement functionality to save the current state of the form in local storage so users can return to the form without losing their progress.

Basic Reordering:

- Allow users to reorder the questions using drag-and-drop (e.g., with a library like react-beautiful-dnd), but focus only on basic reordering of parent questions.

Deliverables

Primary deliverable:

GitHub repository containing the backend project implemented in a suitable framework (for example, Node.js/Express or Python/Flask). The repository should include clear setup and run instructions.
